Hepatitis B virus infection (HBV) is a significant global health problem. Two billion people around the world have contracted the disease, and almost four million cases are a part of the refugee population (Scott et al., 2015). Although screening is mandatory before and after resettlement in the U.S., HBV can still go untreated due to delayed entry into the healthcare system (Museru et al., 2010). Often, there are several challenges working against the refugee population when it comes to healthcare that result in increasing rates of HBV-related morbidity and mortality.

The present study examined the case of a refugee woman who died from liver cancer less than four years after resettlement in Tarrant County. A case study was conducted to illustrate how multi-level influences prevented Mrs. X from receiving adequate and timely care. Information was reviewed from the patient’s medical records, case files from UNTHSC’s Building Bridges Initiative program (funded by the Cancer Prevention Research Institute of Texas), and medical case management files.

Records revealed a possible lack of understanding of the severity of the illness and/or the patient’s inability to advocate for herself. Documentation also supported that there were minimal attempts to reach out to the patient for oncology visits and follow-up appointments after initial diagnosis. When the mass in Mrs. X’s liver was finally re-evaluated, it had grown from 7.3 cm to 13 cm.

Four months before her death, Mrs. X enrolled in the Building Bridges Initiative and was provided medical case management. Mrs. X attended Hepatitis B educational sessions which brought her back into care; she soon agreed to chemotherapy for comfort and started palliative care.

The patient died less than two months after entering hospice. Mrs. X left behind a husband, older children, and a 2 year old child.

Hepatitis B screening and prevalence among resettled refugees (Scott et al., 2010). Hepatitis B virus infection among refugees resettled in the U.S.: High prevalence and challenges in access to health care. Journal of Immigrant Minority Health, 827.

Had the Building Bridges Initiative (BBI) or a similar advocacy and navigation service been in place and accessed at the time of initial diagnosis, the outcome might have been different for Mrs. X.

Medical case management and personnel to advocate on behalf of refugees may be essential to improve coordination of care between the patient and health care provider, as well as help refugee patients navigate the health care system.

**OBJECTIVE**

The present study examined the case of a refugee woman who died from liver cancer less than four years after resettlement in Tarrant County. A case study was conducted to illustrate how multi-level influences prevented Mrs. X from receiving adequate and timely care. Information was reviewed from the patient’s medical records, case files from UNTHSC’s Building Bridges Initiative program (funded by the Cancer Prevention Research Institute of Texas), and medical case management files.

**INTRODUCTION**

Hepatitis B virus infection (HBV) is a significant global health problem. Two billion people around the world have contracted the disease, and almost four million cases are a part of the refugee population (Scott et al., 2015). Although screening is mandatory before and after resettlement in the U.S., HBV can still go untreated due to delayed entry into the healthcare system (Museru et al., 2010). Often, there are several challenges working against the refugee population when it comes to healthcare that result in increasing rates of HBV-related morbidity and mortality.

**RESULTS**

**POLITICAL**

Limited healthcare for refugee population

Did not have health insurance after standard 8 month abidment and before Medicaid for Pregnancy

Refugees considered a vulnerable population

**ORGANIZATIONAL**

**INITIAL DIAGNOSIS:** HBV diagnosis with 7.3 cm mass

Minimal attempts to contact patient for follow up

Patient visited E.R. 8 times for abdomen pain after initial diagnosis; mass in liver never acknowledged during visits

“Loss to follow up” until surgery was scheduled 2 years after diagnosis

Noted in chart that patient would not be eligible for discounted care

**CULTURAL/SOCIETAL**

Community members advised patient against chemotherapy

Believed traditional herb medicine from home country were better than prescribed medications

**INTERPERSONAL**

Strong family support system

Believed in prayer and spiritual healing

**INDIVIDUAL**

Came from an HBV endemic area classified as a developing country

Entered care 2 months after resettlement in U.S.

Positive HBV diagnosis

Missed multiple oncology consultations and follow-up appointments after liver embolization

**DISCUSSION**

Records revealed a possible lack of understanding of the severity of the illness and/or the patient’s inability to advocate for herself. Documentation also supported that there were minimal attempts to reach out to the patient for oncology visits and follow-up appointments after initial diagnosis. When the mass in Mrs. X’s liver was finally re-evaluated, it had grown from 7.3 cm to 13 cm.

Four months before her death, Mrs. X enrolled in the Building Bridges Initiative and was provided medical case management. Mrs. X attended Hepatitis B educational sessions which brought her back into care; she soon agreed to chemotherapy for comfort and started palliative care.

The patient died less than two months after entering hospice. Mrs. X left behind a husband, older children, and a 2 year old child.

**CONCLUSIONS**

Had the Building Bridges Initiative (BBI) or a similar advocacy and navigation service been in place and accessed at the time of initial diagnosis, the outcome might have been different for Mrs. X.

Medical case management and personnel to advocate on behalf of refugees may be essential to improve coordination of care between the patient and health care provider, as well as help refugee patients navigate the health care system.
